Abstract: This paper describes PM SYNCHRONOUS MOTOR Control techniques used in AC drives prevailing in Contemporary market viz, Scalar Control & Vector control(field oriented control). The underlying operating Principle of control schemes are described and indirect vector controlled PM synchronous motor drive has been simulated in MATLAB/Simulink environment. Also hysteresis band pulse width modulated inverter (current controlled VSI) has been implemented using simpower system blocks & the same is used to supply the PM synchronous motor as per the indirect vector control scheme thereby implementing complete indirect vector control drive in closed loop operation.

Index Terms- indirect Vector control, PM synchronous motor, Hysteresis Current controller, Closed loop motor drive.

I. INTRODUCTION

The last decade has seen rapid growth in the field of electrical drives. This growth can be attributed mainly to the advantages offered by both power and signal electronics; hence giving rise to powerful microcontroller and DSP. These technological improvements have allowed the development of very effective AC drives controls.

Now days many industrial applications which require electrical drive demand precise speed and torque control, to increase production quality. More ever proper control of these drives using modern control schemes also improves systems efficiency. For application requiring precise control previously DC drives preferred because of their inherent ability to give independent speed and torque control. But these drives have higher maintenance costs because of brush and commutator construction.

In this paper Vector control technique with Voltage source inverter (VSI) for speed control of PM synchronous motor has been discussed. These drives are simulated in MATLAB and tracking of reference speed and torque has been observed.

II. PM SYNCHRONOUS MOTOR DRIVE SYSTEM

The basic block-diagram of PMSM drive system shown in figure-1 in this figure basic four part divided in this circuit. all part discuss in briefly in this below section in figure-1 shown it is one type of closed-loop block diagram.

![Figure-1 PMSM Drive System [11]](image)

There are four basic component
1. Voltage Source Inverter
2. PM Synchronous Motor
3. Current Controller
4. Position Sensor

Voltage Source Inverter

Voltage Source Inverters are devices that convert a DC voltage to AC voltage of variable frequency and magnitude. They are very commonly used in adjustable speed drives and are characterized by a well defined switched voltage wave form in the terminals. The ac voltage frequency can be variable or constant depends on the application. Three phase inverters consist of six power switches connected as shown in figure to dc voltage source The inverter switches must be carefully selected based on the requirements of operation, ratings and the application.
A permanent magnet synchronous motor (PMSM) is a motor that uses permanent magnets to produce the air gap magnetic field rather than using electromagnets. These motors have significant advantages, attracting the interest of researchers and industry for use in many applications. The properties of the permanent magnet material will affect directly the performance of the motor and proper knowledge is required for the selection of the materials and for understanding PM motors. Permanent magnet (PM) synchronous motors are widely used in low and mid power applications such as computer peripheral equipments, robotics, adjustable speed drives and electric vehicles.

**HYSTERESIS Current Controller**

Current regulators for AC drives are complex because an AC current regulator must control both the amplitude and phase of the stator current. The AC drive current regulator forms the inner loop of the overall motion controller. As such, it must have the widest bandwidth in the system and must, by necessity, have zero or nearly zero steady-state error. Both current source inverters (CSI) and voltage source inverters (VSI) can be operated in controlled current modes. The current source inverter is a "natural" current supply and can readily be adapted to controlled current operation.

The voltage source inverter requires more complexity in the current regulator but offers much higher bandwidth and elimination of current harmonics as compared to the CSI and is almost exclusively used for motion control applications.

Hysteresis current controller can also be implemented to control the inverter currents. The controller will generate the reference currents with the inverter within a range which is fixed by the width of the band gap. In this controller the desired current of a given phase is summed with the negative of the measured current. The error is fed to a comparator having a hysteresis band. When the error crosses the lower limit of the hysteresis band, the upper switch of the inverter leg is turned on. But when the current attempts to become less than the upper reference band, the bottom switch is turned on.
The hysteresis band with the actual current and the resulting gate signals. This controller does not have a specific switching frequency and changes continuously but it is related with the band width shown in figure-3.

**Position Sensor**

Operation of permanent magnet synchronous motors requires position sensors in the rotor shaft when operated without damper winding. The need of knowing the rotor position requires the development of devices for position measurement. There are four main devices for the measurement of position, the potentiometer, linear variable differential transformer, optical encoder and resolvers. The ones most commonly used for motors are encoders and revolvers. Depending on the application and performance desired by the motor a position sensor with the required accuracy can be selected.

**III. VECTOR CONTROL TECHNIQUE**

The PMSM control is equivalent to that of the dc motor by a decoupling control known as field oriented control or vector control. The vector control separates the torque component of current and flux channels in the motor through its stator excitation. The vector control strategy is somewhat similar to that of the induction motor vector control, except for the following:

- The slip frequency is zero because the machine always runs at synchronous speed.
- The magnetizing current \( I_{ds} = 0 \) because the rotor flux is supplied by the PM.
- The unit vector generated from an absolute position sensor because, the unlike slipping poles of an induction motor, the poles are fixed on the rotor.

The basically two method of vector control.(1) Direct method (2) indirect method This method are different essentially by how the unit vector \((\cos \theta, \sin \theta)\) is generated for control. It should be mention here that the orientation of \( I_{ds} \) with rotor flux ,air gap flux or stator flux is possible in vector control. The indirect vector control method is used for the PM synchronous motor drive systems.

**IV. SIMULATION CIRCUIT & RESULT ANALYSIS**

This closed loop simulation done in MATLAB simulation tool. in this circuit VSI inverter with Hysteresis current controller technique is used for closed loop pm synchronous motor drive systems.

Figure-4 Closed loop Vector control of PM Synchronous motor drive system
In figure 4, 5 & 6 is develop in MATLAB simulation software. In this developing the indirect vector control the analysis of stator current, rotor speed and electromagnetic torque. The operation done in constant torque and flux weakening region.

V. CONCLUSION

This paper is given review of PMSM drive system. In this paper also discuss the basic block diagram of PMSM Drive system. Since vector control transforms the PMSM to an equivalent separately excited dc machine, the transfer function between the electric torque and current is linear. In this paper is simulation circuit in MATLAB simulation tool is also present in closed-loop manner using Hysteresis Controller. In this circuit the VSI inverter with HYSTERESIS Current Controlled technique is used and also analysis of rotor speed is increased due-to vector controlled. In this paper is also discussing the vector controlled topology using MATLAB simulation tool, Vector control technique is speed control of PM synchronous motor better than any other control technique like Scalar (v/f) control technique.

APPENDIX
Parameters of PM Synchronous Motor Mathematical model: (using in simulation)

- \( R_s = 4.765\, \text{ohm} \)
- \( L_d = 0.014\, \text{H} \)
- \( L_q = 0.014\, \text{H} \)
- \( J = 0.0001051\, \text{kg}\, m^2 \)
- \( F = 4.047e-005\, \text{N}\, \text{m} \)
- \( p = 2 \)

Other Symbols:
Rs = Stator resistance  
Ld = d-axis inductance  
Lq = q-axis inductance  
J = Rotor interia  
F = Friction factor  
p = Poles pairs
